Xanax is the brand name for **Alprazolam**, a prescription medication that belongs to the **benzodiazepine** class of drugs. It is mainly used to treat **anxiety disorders, panic disorder**, and anxiety linked with depression. Xanax is known for its fast-acting calming effects, which help reduce intense feelings of fear, nervousness, and tension that interfere with daily life.

How Xanax Works in the Body

Xanax works by enhancing the activity of **GABA (Gamma-Aminobutyric Acid)**, a neurotransmitter that slows down brain activity. GABA acts like a natural “brake” for the nervous system. When Xanax boosts GABA’s effects, it helps quiet excessive brain signals, leading to relaxation, reduced anxiety, and a calming sensation. Because it works quickly, Xanax is especially effective for sudden anxiety or panic attacks.

Why Do Doctors Prescribe Xanax?

Doctors prescribe Xanax for conditions such as:

- **Generalized Anxiety Disorder (GAD)**
- **Panic disorder and panic attacks**
- **Short-term anxiety caused by stress or trauma**
- **Anxiety-related sleep disturbances**

Xanax is usually prescribed for **short-term or intermittent use**, as long-term use can increase the risk of dependence.

For this reason, Xanax should only be used under strict medical supervision.
